

The document object is the HTML document that is displayed in that window. These can have many properties and refer to other objects that all out to access or modify document content through DOM or the Document Object Model. The `document.addEventListener()` also you to do something when it is clicked with the mouse by the user. Also, `document.renameNode()` renames the specified node.

My favorite thing to learn in class was how DOM is used to create things like forms and tables on webpages. This really brought to life the full skill needed to create some of these pages. I look forward to learning the simpler way to do this without DOM next week.
